Detection strategies for multi-modal imaging

Why the data sharing is important for us

The problem

Different experimental setups often leads to different values / parameters of the same subject.

AIMS

- to create a database of optical fingerprints and features of molecular, cellular and tissue samples obtained by experimental techniques for **label-free imaging and spectroscopy**
- to build a **coherent source for meta-analysis of validated data** from different labs
- to reveal **correlations between recorded optical signals and their molecular origins**, and physiological, structural and chemical changes in cells and tissues

Selected experimental targets>

Properties and orientation of **collagen fibers**, imaged by NLO/SHG microscopy.

Properties of **NADH** in different physico/chemical environments - model of mechanisms of deexcitation.

Analysis of collagen orientation in tissues

SHG is a well-established technique for characterizing collagen morphology and its organization. However, despite SHG is becoming more and more popular especially among pathologists, a standard method for measuring morphological features of collagen with a quantitative and operator-independent manner **has not been defined yet**.

Problem: it is difficult to compare results obtained in different labs, as the extracted morphological features might be affected by the experimental conditions. Having a standardized method for analysing data is highly desirable and is currently under development.

Methods proposed for analysing SHG images

Fast-Fourier Transform (FFT) and Curvelet transform (CT)

FFT approach is useful to perform an analysis of the spatial frequency components of an image. The distribution of spatial frequencies in the FFT can be used to infer information on the pattern of the original image, hence to characterize the geometry of the image texture.

Healthy dermis

Cicchi et al, J Biophoton (2010)

Keloid

Curvelets represent a generalization of Fourier Transform (FT) that can be used for denoising images and enhancing fiber-edge features. Such property can be exploited by fiber extraction (FIRE) algorithms.

Equine pericardium

Fiber extraction

monitoring of the fiber anisotropy, length and orientation

Grey-level Co-occurrence Matrix (GLCM)

The **GLCM** represents the relationships between neighbors of an intensity matrix (e.g. an image). GLCM-derived functions describe image properties such as contrast and **correlation between adjacent pixels**.

The analysis of the GLCM-correlation function can be used to evaluate the typical size of supra-molecular formations (e.g. the diameter of collagen fibers observed in Second-Harmonic Generation images).

Artificial collagen

Spectral fingerprinting of cardiac myocytes – metabolic imaging

Machine Learning SVM

Quest for molecular origins and functional models

$$S(\lambda)_{\text{sum}} = \sum_{i=1}^3 I_i \times S(\lambda)_i + S(\lambda)_b$$

Metabolic modulation and spectral unmixing „by hand“

Estimated state	SVM method	NMF method
% success	90 - 95	75 - 80

Patterns of metabolic modulation - NAD(P)H in living cardiac cells

Effect of metabolic modulation on fluorescence decay components of cardiomyocyte AF.

The problems

Does better data lead to better science?

What we can learn from biology

In 2014, Nobel Prize laureate Sydney Brenner warned that just focusing on **generating large amounts of very expensive data is not how progress in science is made.**

Compared to (even very large) physics experiment, the biological system is **massively more complex.**

Currently we have **no proper tools to model, or even to understand such complex system.**

We miss fundamental knowledge, no (big) data!
